Beyond a solid state

Sophia Kovalevskaya was born in Moscow on January 3, 1850 and died on February 10, 1891 (according to a 19th-century Russian Calendar).

Sophia was attracted by mathematics at a very young age…These findings were possible. Mathematics was a natural gift, like the aura borealis.

Between 1860 and 1874 Sofia traveled to study mathematics and the natural sciences and sadly discovered that women were not welcomed at any universities, and so she studied only for a few semesters. Finally, she made her way to Karl Weierstrass in Berlin, who was completely baffled by her presence, since a woman willing to study mathematics was extremely unusual. Notwithstanding, he gave her a list of problems to work on, hoping that she would find them too hard and would never return; but she did return, and amazed him with her novel solutions that astonished even the greatest professors in 1889. That same year, on the initiative of Chebyshev, Sofia was awarded a prize by the Paris Academy of Sciences – at the same level of a Fields prize in mathematics –, which was unknown when the winner was a woman.

She was the first female editor, only the second editor of, and the first woman of, Acta Mathematica (founded by Mittag-Leffler); once again a position nobody knew was held by a woman at the time.

She secured a position as professor of mathematics at Stockholm University in Sweden, the first European University to have female professors: Sofia in 1889. That same year, on the initiative of Chebyshev, Sofia was the first woman appointed as Corresponding Member of the Imperial Academy of Sciences. Her last published work was a short article entitled “Sur un théorème de M. Bruns”, in which she gave a new, simpler proof of Bruns’ theorem on a property of the potential function of a homogeneous body.

In 1878, Kovalevskaya gave birth to a daughter, Fufu. In spring 1883, Vladimir, from whom Sofia had been separated for two years, committed suicide. However, Kovalevskaya never abandoned her passion for mathematics. At the time, she continued to learn, quite late though, what so many people around her had already seemed to know from a young age: that life can actually be complete without great success.

In 1874, Kovalevskaya was granted her doctorate, summa cum laude, from Göttingen University. Her dissertation, entitled “On the Theory of Partial Differential Equations,” dealt with a rather general system of differential equations of the first order that admitted any number of variables. This is a remarkable contribution that was published in Crelle’s Journal in 1875. These results are still of importance today and have proved relevant in finding solutions to differential equations with initial conditions; an approach known as the Cauchy problem. The following is a modern version of what is commonly known as the Cauchy–Kovalevskaya Theorem.

A Historical Vision
Sophia Vesilyevna Kovalevskaya ... too much happiness

Many people who have not studied mathematics tend to mistake it as arithmetic and consider it a dry and arid science.

Actually, however, this science requires great fantasy.

Sophia Kovalevskaya’s epigram in Alice Munro’s (2009) novella: Too much happiness

Let a partial differential equation be in the form

$$u_{xx} + u_{yy} = f(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}, ..., u_{x^n y^m})$$

and let the initial conditions

$$u(x_0, y_0) = g_1(x_0, y_0)$$

$$u(x_1, y_1) = g_2(x_1, y_1)$$

Be on the non-characteristic manifold form \( y = y(x) \). If function is analytic in the vicinity of \((x^0, y^0, x^1, y^1, x^2, y^2, ... , x^n, y^n)\), and if the functions \( f \) and \( g \) are analytic in some vicinity of the point \((x^0, y^0, x^1, y^1, x^2, y^2, ... , x^n, y^n)\), then the Cauchy problem has a unique solution in some vicinity of the point \((x^0, y^0, x^1, y^1, x^2, y^2, ... , x^n, y^n)\).

The preceding statement seems equally applicable to hyperbolic, elliptic, and parabolic equations. However, we shall see that difficulties arise in formulating the Cauchy problem for non-hyperbolic equations.

Kovalevskaya also wrote about the achievement of having her work (on the refraction of light in crystals) published in Acta Mathematica; a masterpiece including the Reduction of a Definite Integral of Abelian Integrals of Third Range. The supplementary Research and Observations on Laplace’s work on the Form of Saturn Rings, and also on particular Properties of a System of Equations.

Apart from the remarkable achievements mentioned above, the highest point in Sofia's career came on Christmas Eve 1889, when she presented a solution to the problem of rotation of a solid body about a fixed point under gravitational force. Such a solution was worth the price Bondin, an award granted by the Paris Academy of Sciences – at the same level of a Fields prize in mathematics - where it was unknown that the winner was a woman.
